Abstract

The Berezinsky-Kosterlitz-Thouless (BKT) RG flow in the ensemble of monopoles existing in the finite-temperature (2+1)D Georgi-Glashow model is explored in the regime when the Higgs field is not infinitely heavy, but its mass is rather of the same order of magnitude as the mass of the W-boson. The corrections to the standard RG flow are derived to the leading order in the inverse mass of the Higgs boson. According to the obtained RG equations, the scaling of the free-energy density in the critical region and the value of the critical temperature of the phase transition are found to be unaffected by the finiteness of the Higgs-boson mass. The evolution of the Higgs mass itself is also investigated and shown to be rather weak, that enables one to treat this parameter as a constant. The same analysis is further performed in the SU(N)-case at N > 2, where the RG invariance is demonstrated to hold only approximately, in a certain sense. Modulo this approximation, the critical behaviour of the SU(N)-model turns out to be identical to that of the SU(2)-one.

1 Introduction. The model.

The (2+1)-dimensional Georgi-Glashow model is known as an example of the theory allowing for an analytic description of confinement \[1\]. Besides the investigations performed in the compact-QED limit of this model (where the Higgs boson is infinitely heavy), there have recently also been done several investigations of the Georgi-Glashow model beyond that limit \[2, 3\]. The analysis of ref. \[2\] has been carried out in the Bogomolny-Prasad-Sommerfield (BPS) limit \[4\], that is the limit where the Higgs field is much lighter than the W-boson. In that paper, the theory has been investigated both at zero and nonzero temperatures. In ref. \[3\], the zero-temperature results of ref. \[2\] have been generalized to the case intermediate between the BPS- and the compact-QED limits of the model, when the mass of

\*E-mail: antonov@df.unipi.it
†Permanent address: ITEP, B. Cheremushkinskaya 25, RU-117 218 Moscow, Russia.
the Higgs boson is of the same order of magnitude as the mass of the W-boson. The aim of the present letter is to generalize to this case also the finite-temperature results of ref. [3]. In this way, we shall address the corrections to the RG behaviour of the monopole ensemble, existing in the model, which stem from the finiteness of the Higgs-boson mass. This will be done in the next Section. In Section 3, these results will be generalized to the case of the \( SU(N) \) Georgi-Glashow model. The main results of the letter will finally be summarized in the Conclusions.

The Euclidean action of the \((2+1)D\) Georgi-Glashow model reads [1]

\[
S = \int d^3 x \left[ \frac{1}{4g^2} (F_{\mu\nu})^2 + \frac{1}{2} (D_\mu \Phi^a)^2 + \frac{\lambda}{4} \left( (\Phi^a)^2 - \eta^2 \right)^2 \right].
\]

Here, the Higgs field \( \Phi^a \) transforms by the adjoint representation, \( D_\mu \Phi^a \equiv \partial_\mu \Phi^a + \varepsilon^{abc} A_\mu^b \Phi^c \). Next, \( \lambda \) is the Higgs coupling constant of dimensionality [mass], \( \eta \) is the Higgs v.e.v. of dimensionality [mass]\(^{1/2} \), and \( g \) is the electric coupling constant of the same dimensionality. At the one-loop level, the partition function describing the sector of the theory [1] which contains dual photons and Higgs bosons reads [3]

\[
Z = 1 + \sum_{N=1}^{\infty} \frac{\zeta^N}{N!} \left( \prod_{i=1}^{N} \int d^3 z_i \sum_{q_i=\pm 1} \right) \exp \left[ -\frac{g^2}{8\pi} \sum_{a,b=1}^{N} \left( \frac{q_a q_b}{|z_a - z_b|} - \frac{e^{-m_H|z_a - z_b|}}{|z_a - z_b|} \right) \right] \equiv \int D\chi D\psi e^{-S},
\]

where

\[
S = \int d^3 x \left[ \frac{1}{2} (\partial_\mu \chi)^2 + \frac{1}{2} (\partial_\mu \psi)^2 + \frac{m_H^2}{2} \psi^2 - 2\zeta e^{g_{\psi}\psi} \cos(g_m \chi) \right] \equiv \int d^3 x L[\chi, \psi | g_m, \zeta].
\]

The partition function (2) describes the grand canonical ensemble of monopoles with the account for their Higgs-mediated interaction. In eqs. (3) and (4), \( \chi \) is the dual-photon field, and the field \( \psi \) accounts for the Higgs field, whose mass reads \( m_H = \eta \sqrt{2\lambda} \). Note that from eq. (3) it is straightforward to deduce that when \( m_H \) formally tends to infinity, one arrives at the conventional sine-Gordon theory of the dual-photon field [1] describing the compact-QED limit of the model. Next, in the above equations, \( g_m \) stands for the magnetic coupling constant related to the electric one as \( g_m g = 4\pi \), and the monopole fugacity \( \zeta \) has the form:

\[
\zeta = \frac{m_W^{7/2}}{g} \delta \left( \frac{\lambda}{g^2} \right) e^{-4\pi m_W \epsilon / g^2}.
\]

In this formula, \( m_W = g\eta \) is the W-boson mass, and \( \epsilon = \epsilon(\lambda / g^2) \) is a certain slowly varying function, \( \epsilon \geq 1, \epsilon(0) = 1 \) [4], \( \epsilon(\infty) \simeq 1.787 \) [5]. As far as the function \( \delta \) is concerned, it is determined by the loop corrections. In what follows, we shall work in the standard weak-coupling regime \( g^2 \ll m_W \), which parallels the requirement that \( \eta \) should be large enough to ensure the spontaneous symmetry breaking from \( SU(2) \) to \( U(1) \).

It is worth emphasizing that the phase transition to be explored in this letter is the finite-temperature BKT phase transition [1] (for a review see e.g. [3]) in the monopole ensemble, rather than the real deconfining phase transition in the model [1]. The latter has been recently shown [3] to be associated with the deconfinement of W-bosons, and those are not described by the action (4). As far as the influence of the Higgs field to the deconfining phase transition is concerned, it has been addressed in ref. [10].
At finite temperature $T \equiv 1/\beta$, one should supply the fields $\chi$ and $\psi$ with the periodic boundary conditions in the temporal direction, with the period equal to $\beta$. Because of that, the lines of the magnetic field emitted by a monopole cannot cross the boundary of the one-period region and consequently, at the distances larger than $\beta$, should go almost parallel to this boundary, approaching it. Therefore, monopoles separated by such distances interact via the 2D Coulomb potential, rather than the 3D one. Since the average distance between monopoles in the plasma is of the order of $\zeta^{-1/3}$, we see that at $T \geq \zeta^{-1/3}$, the monopole ensemble becomes two-dimensional. Owing to the fact that $\zeta$ is exponentially small in the weak-coupling regime under discussion, the idea of dimensional reduction is perfectly applicable at the temperatures of the order of the critical temperature of the BKT phase transition in the monopole plasma, which is equal to $g^2/2\pi$ \[11\]. The factor $\beta$ at the action of the dimensionally-reduced theory, $S_{d-r.} = \beta \int d^2x\mathcal{L}[\chi, \psi|g_m, \zeta]$, can be removed [and this action can be cast to the original form of eq. (3) with the substitution $d^3x \rightarrow d^2x$] by the obvious rescaling: $S_{d-r.} = \int d^2x\mathcal{L} [\chi^{\text{new}}, \psi^{\text{new}}|\sqrt{K}, \zeta]$. Here, $K \equiv g_m^2 T$, $\xi \equiv \beta \zeta$, $\chi^{\text{new}} = \sqrt{\beta} \chi$, $\psi^{\text{new}} = \sqrt{\beta} \psi$, and in what follows we shall denote for brevity $\chi^{\text{new}}$ and $\psi^{\text{new}}$ simply as $\chi$ and $\psi$, respectively.

As it has already been mentioned, the RG analysis of the BKT phase transition in the BPS limit, $m_H \ll m_W$, has been performed in ref. \[2\]. Since the characteristic momenta of the field $\psi$ are of the order of $m_H$, in that limit one may not be interested in the renormalization of the field $\psi$. Instead, it is possible to integrate this field out in the original 3D theory at the very beginning and then to explore the RG behaviour of the resulting action of the dual-photon field at finite temperature. In the present letter, we shall explore the RG behaviour of the model in the regime intermediate between the BPS- and the compact-QED limits, $m_H \sim m_W$. Clearly, in such a case one should take into account the renormalization of the field $\psi$. As well as in ref. \[2\], there will be derived the RG equation describing the evolution of $m_H$. However, due to the largeness of $m_H$ with respect to the characteristic momentum scale we are working at (since $m_H$ is of the order of the UV cutoff $m_W$), this evolution will be shown to be rather weak.

2 RG analysis in the SU(2)-case.

In what follows, we shall adapt the usual RG strategy \[12\] based on the integration over the high-frequency modes. Note that this procedure will be applied to all the fields, i.e., not only to $\chi$, but also to $\psi$. Splitting the momenta into two ranges, $0 < p < \Lambda'$ and $\Lambda' < p < \Lambda$, one can define the high-frequency modes as $h = \chi_\Lambda - \chi_{\Lambda'}$, $\phi = \psi_\Lambda - \psi_{\Lambda'}$, where $\mathcal{O}_{\Lambda'}(x) = \int \frac{d^3 p}{(2\pi)^3} e^{i px} \mathcal{O}(p)$ and consequently, e.g., $h(x) = \int_{\Lambda' < p < \Lambda} \frac{d^3 p}{(2\pi)^3} e^{i px} \chi(p)$. The partition function,

$$Z_\Lambda = \int_{0 < p < \Lambda} D\chi(p) D\psi(p) \exp \left\{ -S_{d-r.}[\chi_\Lambda, \psi_\Lambda] \right\},$$

can be rewritten as follows:

$$Z_\Lambda = \int_{0 < p < \Lambda'} D\chi(p) D\psi(p) \exp \left[ \frac{1}{2} \int d^2 x \chi_{\Lambda'} \partial^2 \chi_{\Lambda'} + \frac{1}{2} \int d^2 x \psi_{\Lambda'} \left( \partial^2 - m_H^2 \right) \psi_{\Lambda'} \right] Z',$$

where
\[ Z' = \int A' < p < A \mathcal{D}\chi(p)\mathcal{D}\psi(p) \exp \left[ \frac{1}{2} \int d^2 x h \partial^2 h + \frac{1}{2} \int d^2 x \phi \left( \partial^2 - m_H^2 \right) \phi + 2\xi e^{\sqrt{K} \psi_{\Lambda'}} \cos \left( \sqrt{K} (\chi_{A'} + h) \right) \right] . \]

Owing to the exponential smallness of the fugacity, \( Z' \) can further be expanded as
\[ Z' \simeq 1 + 2\xi \int d^2 x \left( e^{\sqrt{K} \psi_{\Lambda'}} \right) \langle \cos (\sqrt{K} (\chi_{A'} + h)) \rangle_h + 2\xi^2 \int d^2 x d^2 y x \times \left[ \left( e^{\sqrt{K} \psi_{\Lambda'}(x) + \phi(x))} e^{\sqrt{K} \psi_{\Lambda'}(y) + \phi(y)} \right) \langle \cos \left( \sqrt{K} (\chi_{A'}(x) + h(x)) \right) \cos \left( \sqrt{K} (\chi_{A'}(y) + h(y)) \right) \rangle_h - \langle e^{\sqrt{K} \psi_{\Lambda'}(x) + \phi(x))} \langle e^{\sqrt{K} \psi_{\Lambda'}(y) + \phi(y)} \rangle \langle \cos \left( \sqrt{K} (\chi_{A'}(x) + h(x)) \right) \langle \cos \left( \sqrt{K} (\chi_{A'}(y) + h(y)) \right) \rangle_h \right], \]

where
\[ \langle O \rangle_h = \int \mathcal{D}\chi(p) \exp \left( \frac{1}{2} \int d^2 x h \partial^2 h \right) \mathcal{O}, \quad \langle O \rangle_\phi = \int \mathcal{D}\psi(p) \exp \left[ \frac{1}{2} \int d^2 x \phi \left( \partial^2 - m_H^2 \right) \phi \right] \mathcal{O} . \]

Carrying out the averages we arrive at the following expression for \( Z' \):
\[ Z' \simeq 1 + 2\xi A(0) B(0) \int d^2 x e^{\sqrt{K} \psi_{\Lambda'}} \cos \left( \sqrt{K} \chi_{A'} \right) + (\xi A(0) B(0))^2 \int d^2 x d^2 y x \times e^{\sqrt{K} \psi_{\Lambda'}(x) + \psi_{\Lambda'}(y)} \sum_{k=\pm 1} \left[ A^{2k}(x - y) B^2(x - y) - 1 \right] \cos \left[ \sqrt{K} (\chi_{A'}(x) + k\chi_{A'}(y)) \right] , \quad (5) \]

where
\[ A(x) \equiv e^{-K g_{h}(x)/2}, \quad B(x) \equiv e^{K g_{\phi}(x)/2}, \quad G_{h}(x) = \int_{A' < p < A} \frac{d^2 p}{(2\pi)^2} \frac{e^{ipx}}{p^2}, \quad G_{\phi}(x) = \int_{A' < p < A} \frac{d^2 p}{(2\pi)^2} \frac{e^{ipx}}{p^2 + m_H^2} . \]

Since in what follows we shall take \( A' = A - dA \), the factors \( \left[ A^{2k}(x - y) B^2(x - y) - 1 \right], k = \pm 1 \), are small. Owing to this fact, it is convenient to introduce the coordinates \( r \equiv x - y \) and \( R \equiv \frac{1}{2}(x + y) \), and Taylor expand eq. (5) in powers of \( r \). Clearly, this expansion should be performed up to the induced-interaction term \( \sim \xi^2 \int d^2 x e^{2\sqrt{K} \psi_{\Lambda'}(R)} \cos \left( 2\sqrt{K} \chi_{A'}(R) \right) \), that should already be disregarded. As a result, we obtain the following expression for \( Z_{A'} \)\footnote{For the sake of uniformity, we replace \( d^2 R \) by \( d^2 x \).}:

\[ Z_{A'} = \int \mathcal{D}\chi(p)\mathcal{D}\psi(p) \exp \left\{ \frac{1}{2} \int d^2 x \psi_{\Lambda'} \left( \partial^2 - m_H^2 \right) \psi_{\Lambda'} + a_3(\xi A(0) B(0))^2 \int d^2 x e^{2\sqrt{K} \psi_{\Lambda'}} - \right\} . \]
\[-\frac{1}{2} \int d^2x \left[ 1 + a_2 (\xi A(0) B(0))^2 \frac{K}{2} e^{2\sqrt{K} \psi_\Lambda'} \right] (\partial_\mu \chi_{\Lambda'})^2 + 2\xi A(0) B(0) \int d^2x e^{\sqrt{K} \psi_\Lambda'} \cos \left( \sqrt{K} \chi_{\Lambda'} \right) \right], \]  

where we have used the notations similar to those of ref. \cite{12}.

\[ a_2 \equiv \int d^2r r^2 \left[ A^{-2}(r) B^2(r) - 1 \right], \quad a_3 \equiv \int d^2r \left[ A^{-2}(r) B^2(r) - 1 \right]. \]  

Taking into account that \( \Lambda' = \Lambda - d\Lambda \) it is straightforward to get

\[ a_2 = \alpha_2 K \frac{d\Lambda}{\Lambda^2} \left( 1 + \frac{\Lambda^2}{m_H^2} \right), \quad a_3 = \alpha_3 K \frac{d\Lambda}{\Lambda^3} \left( 1 + \frac{\Lambda^2}{m_H^2} \right). \]

Here, \( \alpha_{2,3} \) stand for some momentum-space-slicing dependent positive constants, whose concrete values will turn out to be unimportant for the final expressions describing the RG flow.

Next, since \( a_{2,3} \) occur to be infinitesimal (because they are proportional to \( d\Lambda \)), the terms containing these constants on the r.h.s. of eq. (6) can be treated in the leading-order approximation of the cumulant expansion that we shall apply for the average over \( \psi \). In fact, we have

\[
\int_{0 < p < \Lambda'} D\psi(p) \exp \left[ \frac{1}{2} \int d^2 x \psi_\Lambda' \left( \partial^2 - m_H^2 \right) \psi_\Lambda' \right] \exp \left( b \int d^2 x e^{2\sqrt{K} \psi_\Lambda'} f(x) \right) \simeq \exp \left[ b e^{2K G(0)} \int d^2 x f(x) + \frac{b^2}{2} e^{4K G(0)} \int d^2 x d^2 y \left( e^{4K G(x-y)} - 1 \right) f(x) f(y) \right],
\]

where \( f \) is equal either to unity or to \( (\partial_\mu \chi_\Lambda')^2 \), \( b \sim a_{2,3} (\xi A(0) B(0))^2 \), and

\[ G(x) \equiv \int_{0 < p < \Lambda'} \frac{d^2p}{(2\pi)^2} \frac{e^{ipx}}{p^2 + m_H^2}, \quad G(0) = \frac{1}{4\pi} \ln \left( 1 + \frac{\Lambda^2}{m_H^2} \right). \]

In order to estimate the parameter of the cumulant expansion, \( \kappa \equiv b e^{2K G(0)} \int d^2 x \left( e^{4K G(x)} - 1 \right) \), note that we are working in the phase where monopoles form the plasma, i.e., below the BKT critical temperature \( T_c = g^2 / 2\pi \). By virtue of this fact, \( 4K |G(x)| \leq 32\pi (\Lambda'/m_H)^2 \), that due to the factor \( (\Lambda'/m_H)^2 \) is generally much smaller than unity. Owing to that, we get

\[
\kappa \simeq b \left( 1 + \frac{\Lambda^2}{m_H^2} \right)^{4\pi} 4K \int d^2 x G(x) \simeq \frac{2bK}{\pi m_H^2} \left[ 1 + \frac{K}{2\pi} \left( \frac{\Lambda'}{m_H} \right)^2 \right].
\]

Choosing for concreteness \( b = a_3 (\xi A(0) B(0))^2 \) and taking into account that

\[
A(0) \simeq 1 - \frac{K}{2} G_\xi(0) = 1 - \frac{K}{4\pi} \frac{d\Lambda}{\Lambda}, \quad B(0) \simeq 1 + \frac{K}{2} G_\phi(0) \simeq 1 + \frac{K}{4\pi} \left( \frac{\Lambda}{m_H} \right)^2 \frac{d\Lambda}{\Lambda},
\]

we obtain to the leading order: \( \kappa \simeq 2a_3 K \xi^2 / (\pi m_H^2) \). This quantity possesses the double smallness—firstly, because \( a_3 \) is infinitesimal, and secondly, due to the exponential smallness of \( \xi \).

Such an extremely rapid convergence of the cumulant expansion then enables us to replace \( e^{2\sqrt{K} \psi_\Lambda'} \) in the terms proportional to \( a_{2,3} \) on the r.h.s. of eq. (6) by the average value of this exponent equal to \( \left( 1 + \frac{\Lambda^2}{m_H^2} \right)^{4\pi} \). Comparing the so-obtained expression with the initial one, we arrive at the following renormalizations of the fields and parameters of the Lagrangian:
\[ \chi_{\lambda'}^{\text{new}} = C \chi'_{\lambda'}, \psi_{\lambda'}^{\text{new}} = C \psi'_{\lambda'}, \quad K^{\text{new}} = \frac{K}{C^2}, \quad \mu^{\text{new}} = \frac{\mu}{C^2}, \quad \xi^{\text{new}} = A(0) B(0) \xi, \quad (9) \]

where

\[ \mu \equiv m_H^2, \quad C \equiv \sqrt{1 + \frac{K a_2}{2} (\xi A(0) B(0))^2 \left(1 + \frac{\Lambda^2}{m_H^2}\right)^2}, \quad \approx \sqrt{1 + \frac{K a_2}{2} (\xi A(0) B(0))^2 \left(1 + \frac{\Lambda^2}{m_H^2} K^{\text{new}}\right)^2}. \quad (10) \]

Besides that, we obtain the following shift of the free-energy density \( F \equiv -\frac{\ln Z'}{V} \):

\[ F = F^{\text{new}} - a_3 (\xi A(0) B(0))^2 \left(1 + \frac{\Lambda^2}{m_H^2}\right)^2 \quad \approx \quad F^{\text{new}} - a_3 (\xi A(0) B(0))^2 \left(1 + \frac{K \Lambda^2}{2 \pi m_H^2}\right), \quad (11) \]

where \( V \) is the 2D-volume (i.e., area) of the system.

By making use of the relations (8), it is further straightforward to derive from eqs. (12)-(14) the RG equations in the differential form. Those read

\[ d\xi = -\frac{K \xi}{4\pi} \left(1 - \frac{\Lambda^2}{\mu}\right) \frac{d\Lambda}{\Lambda}, \quad dK = -\frac{\alpha_2}{2} K^3 \xi^2 \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{\Lambda^2}{\mu}\right] \frac{d\Lambda}{\Lambda}, \]

\[ d\mu = -\frac{\alpha_2}{2} (K \xi)^2 \mu \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{\Lambda^2}{\mu}\right] \frac{d\Lambda}{\Lambda}, \quad dF = \alpha_3 K \xi^2 \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{\Lambda^2}{\mu}\right] \frac{d\Lambda}{\Lambda}. \]

Following the notations of ref. [12], we shall further make the change of variables from the momentum scale to the real-space one: \( \Lambda \rightarrow a \equiv 1/\Lambda, \quad d\Lambda \rightarrow -d\Lambda \), that obviously modifies the above equations as

\[ d\xi = -\frac{K \xi da}{4\pi} \left(1 - \frac{1}{\mu a^2}\right), \quad (12) \]

\[ dK = -\frac{\alpha_2}{2} K^3 \xi^2 a^3 da \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{1}{\mu a^2}\right], \quad (13) \]

\[ d\mu = -\frac{\alpha_2}{2} (K \xi)^2 \mu a^3 da \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{1}{\mu a^2}\right], \quad (14) \]

\[ dF = \alpha_3 K \xi^2 a da \left[1 + \left(\frac{K}{2\pi} + 1\right) \frac{1}{\mu a^2}\right]. \quad (15) \]

Our main aim below is to derive from eqs. (12)-(15) the leading-order corrections in \( (\mu a^2)^{-1} \) to the BKT RG flow in the vicinity of the critical point. This point is known to be \( K_{cr}^{(0)} = 8\pi, \quad y_{cr}^{(0)} = 0 \), where \( y \equiv \xi a^2 \), and the superscript \( "(0)" \) denotes the zeroth order in the \( (\mu a^2)^{-1}\)-expansion. These values of \( K_{cr}^{(0)} \) and \( y_{cr}^{(0)} \) will be recovered below. Besides that, it will be demonstrated that in the critical region, \( \mu \) is evolving very weakly. Owing to this fact, the initial assumption on the largeness of \( \mu \) (namely, that it is of the order of \( m_W^2 \)), will be preserved by the RG flow, at least in that region. This enables us to treat \( \mu \) almost as a constant and seek for the corrections to the RG flow of \( K^{(0)} \) in powers of \( (\mu a^2)^{-1} \). The zeroth-order equation stemming from eq. (13) then reads

\[ dK^{(0)} = -\frac{\alpha_2}{2} K^{(0)} 3 \xi^2 a^3 da. \quad (16) \]
Respectively, the zeroth-order in \((\mu a^2)^{-1}\) equation for \(y\) has the form

\[ dy^{(0)} = 2\frac{da}{a} y^{(0)} x, \]

where \(x \equiv 2 - \frac{K^{(0)}}{4\pi} \). Equations (19) and (17) yield the above-mentioned leading critical value of \(K, K_{cr}^{(0)} \). Note that the respective critical temperature following from this value is equal to \(T_c \). Next, with this value of \(K_{cr}^{(0)} \), eq. (16) can be rewritten in the vicinity of the critical point as

\[ dx = (8\pi)^2 \alpha_2 \xi^2 a^3 da. \]

Introducing further instead of \(y\) the new variable \(z = (8\pi)^2 \alpha_2 y^2\) and performing the rescaling \(a^{new} = a\sqrt{8\pi\alpha_2/\alpha_3}\) we get from eqs. (13), (17), and (18) the following system of equations:

\[ dz^{(0)} = 2\frac{da}{a} x z^{(0)}, \quad dx = z^{(0)} \frac{da}{a}, \quad dF^{(0)} = z^{(0)} \frac{da}{a^3}. \]

These equations yield the standard RG flow in the vicinity of the critical point, \(x = z^{(0)} = 0\), which reads \(z^{(0)} - x^2 = \tau\), where \(\tau \propto (T_c - T)/T_c\) is some constant. In particular, \(x \simeq \sqrt{\tau}\) at \(T \to T_c - 0\). Owing to the first of eqs. (15) this relation yields \((z^{(0)})^{-1/2} - (z^{(0)})^{-1/2} = \ln (a/a_{in})\), where the superscription “in” means the initial value. Taking into account that \(z_{in}^{(0)}\) is exponentially small, while \(z^{(0)} \sim 1\) (the value at which the growth of \(z^{(0)}\) stops), we obtain in the case \(x_{in} \leq \sqrt{\tau}\):

\[ \ln (a/a_{in}) \sim (z_{in}^{(0)})^{-1/2} \sim \tau^{-1/2}. \]

According to this relation, at \(T \to T_c - 0\), the correlation radius diverges with an essential singularity as \(a(\tau) \sim \exp (\text{const}/\sqrt{\tau})\). (In the molecular phase, the correlation radius becomes infinite due to the short-rangeness of the molecular fields.) As far as the leading part of the free-energy density is concerned, it scales as \(F^{(0)} \sim a^{-2}\) and therefore remains continuous in the critical region. Moreover, the correction to this behaviour stemming from the finiteness of the Higgs-boson mass [the last term on the r.h.s. of eq. (13)] is clearly of the same functional form, \(\sim \exp (-\text{const}'/\sqrt{\tau})\), i.e., it is also continuous.

We are now in the position to address the leading-order \([\ln (\mu a^2)^{-1}]\) corrections to the above-discussed BKT RG flow of \(K^{(0)}\) and \(z^{(0)}\). To this end, let us represent \(K\) and \(Z\) as \(K = K^{(0)} + K^{(1)}/(\mu a^2), z = z^{(0)} + z^{(1)}/(\mu a^2)\), that by virtue of eqs. (12) and (13) leads to the following novel equations:

\[ dK^{(1)} = -2K^{(1)} \frac{da}{a} = -4\pi \frac{da}{a} \left( z^{(0)} + z^{(1)} \frac{K^{(0)}}{\mu a^2} \right) \left( 1 + \frac{K^{(0)}}{2\pi} + \frac{3K^{(1)}}{K^{(0)}} \right), \]

\[ dz^{(1)} = -2z^{(1)} \frac{da}{a} = -2 \frac{da}{a} \left[ z^{(1)} \frac{K^{(0)}}{4\pi} - 2 \right] + z^{(0)} \frac{K^{(1)}}{4\pi} \left( K^{(1)} - K^{(0)} \right). \]

In the vicinity of the critical point, we can insert into eq. (21) the above-obtained critical values of \(K^{(0)}\) and \(z^{(0)}\), that yields:

\[ dz^{(1)} = 2z^{(1)} \frac{da}{a}. \]
Therefore, \( z^{(1)} = C_1 a^2 \), where \( C_1 \) is the integration constant of dimensionality \((\text{mass})^2\), \( C_1 \ll \mu \).

Inserting further this solution into eq. (20), considered in the vicinity of the critical point, we obtain the following equation:

\[
dK^{(1)} - 2K^{(1)} \frac{da}{a} = - \frac{4\pi C_1}{\mu} \frac{da}{a} \left( \frac{3K^{(1)}}{8\pi} + 5 \right).
\] (23)

Its integration is straightforward and yields

\[
K^{(1)} = C_2 \left( \mu a^2 \right)^{\frac{3C_1}{4\mu}} + \frac{40\pi C_1}{4\mu - 3C_1},
\] (24)

where the dimensionless integration constant \( C_2 \) should be much smaller than \((\mu a^2)^{\frac{3C_1}{4\mu}}\). [Note that the last addendum in eq. (24) is positive.] Therefore, the total correction, \( K^{(1)}/(\mu a^2) \), approximately scales with \( a \) in the critical region as \( \frac{40\pi C_1}{4\mu - 3C_1} \). We see that at the critical point, this expression vanishes due to the divergence of the correlation radius. Note also that eq. (24) can obviously be rewritten as the following dependence of \( K^{(1)}/(\mu a^2) \) on \( z^{(1)} \) (\( z^{(1)} \ll \mu a^2 \)):

\[
\frac{K^{(1)}}{\mu a^2} = C_2 \left( \mu a^2 \right)^{-\frac{3C_1}{4\mu a^2}} + \frac{40\pi z^{(1)}}{4\mu a^2 - 3z^{(1)}} \mu a^2.
\]

With the above-discussed critical behaviour of the correlation radius, \( a(\tau) \), this relation determines the correction to the BKT RG flow, \( z^{(0)} = (2 - K^{(0)}/4\pi)^2 = \tau \).

Clearly, the critical values of \( z^{(1)} \) and \( K^{(1)} \) determined by the fixed point of eqs. (23) and (20) [or (23)] read \( z^{(1)}_{\text{cr}} = K^{(1)}_{\text{cr}} = 0 \). This means that the finiteness of the Higgs-boson mass does not change the value of the BKT critical temperature, \( T_c \). Note that this fact can also be seen by the evaluation of the mean squared separation in the monopole-antimonopole molecule. The expression for this quantity stems from the statistical weight in the monopole ensemble, which at finite temperature reads [cf. eq. (2)]

\[
\exp \left[ \frac{K}{4\pi} \sum_{a,b=1}^{N} (q_a q_b \ln (\bar{\mu} |z_a - z_b|)) + K_0 (m_H |z_a - z_b|) \right].
\]

Here, \( \bar{\mu} \) stands for the IR cutoff, \( K_0 \) is the modified Bessel function, and \( z_{a,b} \) are the 2D-vectors. The desired mean squared separation is then given by the following formula:

\[
\langle L^2 \rangle = \frac{\int_{|x| > m_H^{-1}} d^2x |x|^{2-\frac{8\pi T}{g^2}} \exp \left[ \frac{4\pi T}{g^2} K_0 (m_H |x|) \right]}{\int_{|x| > m_H^{-1}} d^2x |x|^{\frac{8\pi T}{g^2}} \exp \left[ \frac{4\pi T}{g^2} K_0 (m_H |x|) \right]}.
\]

In the case \( m_H \sim m_W \) under study, the exponential factors in the numerator and denominator of this equation can be disregarded, and we obtain \( \langle L^2 \rangle \simeq \frac{4\pi T - g^2}{2m_W^2 [2\pi T - g^2]} \), that yields the value of the critical temperature equal to \( T_c \). Besides that, it is straightforward to see that in the weak-coupling regime under study, the value of \( \sqrt{\langle L^2 \rangle} \) is exponentially smaller than the characteristic distance in the monopole plasma, \( \zeta^{-1/3} \), i.e., molecules are very small-sized with respect to that distance.

Finally, in order to justify the above-adapted approximation under which \( \mu \) was treated as a constant, we should check that under the RG flow, it is really evolving only weakly. To this end, let us pass in
considered in the critical region, from the variable $\xi$ to the above-introduced variable $z$ and perform again the rescaling $a \to a^{\text{new}}$. This yields $\frac{d\mu}{\mu} = -\frac{\bar{z}}{2} \frac{da}{a}$ or $d\mu = -\frac{C_1}{2} \frac{da}{a}$. Since $C_1 \ll \mu$, we conclude that $\frac{|d\lambda|}{\mu} \ll \frac{da}{a}$. This inequality means that in the vicinity of the BKT critical point, $\mu$ is really evolving weakly. This justifies its treatment as a large (with respect to $\Lambda^2$) constant quantity, approximately equal to its initial value of the order of $m_W^2$.

3 SU(N)-case.

The $SU(N)$-generalization of the action (3), stemming from the $SU(N)$ Georgi-Glashow model, has the form

$$S = \int d^3x \left[ \frac{1}{2} (\partial_{\mu} \tilde{\chi})^2 + \frac{1}{2} (\partial_{\mu} \psi)^2 + \frac{m_H^2}{2} \psi^2 - 2 \zeta e^{\eta \psi} \sum_i \cos \left( g_m \tilde{q}_i \tilde{\chi} \right) \right].$$ (25)

Here, $\sum \equiv \sum_{i=1}^{N(N-1)/2}$, and $\tilde{q}_i$’s are the positive root vectors of the group $SU(N)$. As well as the field $\tilde{\chi}$, these vectors are $(N-1)$-dimensional. Note that the $SU(3)$- and the general $SU(N)$-versions of the action (23), thus incorporating the effects of the Higgs field, have been discussed in refs. [2, 8]. The compact-QED limit of the $SU(N)$-case has been studied (at zero temperature) in refs. [13] and [14].

Here, similarly to all the above-mentioned papers, we have assumed that W-bosons corresponding to different root vectors have the same masses.

Considering the action (25) at finite temperature and applying to the resulting dimensionally-reduced theory the RG procedure of the previous Section, we arrive at the following analogue of eq. (6):

$$Z_\Lambda = \int_{0 < \rho < \Lambda'} D\tilde{\chi}(p) D\psi(p) \exp \left\{ \frac{1}{2} \int d^2x \psi_N \left( \partial^2 - m_H^2 \right) \psi_N + (\xi A(0) B(0))^2 \int d^2x e^{2\sqrt{K} \psi_N} \sum_{ij} a^{ij}_{ij} \times \right. 
\left. \cos \left[ \sqrt{K} (\tilde{q}_i - \tilde{q}_j) \tilde{\chi}_N \right] + 2 \xi A(0) B(0) \int d^2x e^{\sqrt{K} \psi_N} \sum_i \cos \left( \sqrt{K} \tilde{q}_i \tilde{\chi}_N \right) - \frac{1}{2} \int d^2x \delta^{ab} + \right. 
\left. + (\xi A(0) B(0))^2 \frac{K}{8} e^{2\sqrt{K} \psi_N} \sum_{ij} a^{ij}_{ij} (\tilde{q}_i + \tilde{q}_j) \alpha (\tilde{q}_i + \tilde{q}_j) \beta \cos \left[ \sqrt{K} (\tilde{q}_i - \tilde{q}_j) \tilde{\chi}_N \right] \left( \partial_{\mu} \chi^{\alpha}_{N} \right) \left( \partial_{\mu} \chi^{\beta}_{N} \right) \right\}. \quad (26)$$

Here, $\alpha, \beta = 1, \ldots, (N-1)$, and we have introduced the notations similar to (7),

$$a^{ij}_{ij} \equiv \int d^2r r^2 \left[ B^2(r) e^{K \tilde{q}_i \tilde{q}_j G_h(r)} - 1 \right], \quad a^{ij}_{3} \equiv \int d^2r \left[ B^2(r) e^{K \tilde{q}_i \tilde{q}_j G_h(r)} - 1 \right],$$

so that at $\Lambda' = \Lambda - d\Lambda$,

$$a^{ij}_{2} = \alpha_2 K \frac{d\Lambda}{\Lambda^5} \left( \tilde{q}_i \tilde{q}_j + \frac{\Lambda^2}{m_H^2} \right), \quad a^{ij}_{3} = \alpha_3 K \frac{d\Lambda}{\Lambda^5} \left( \tilde{q}_i \tilde{q}_j + \frac{\Lambda^2}{m_H^2} \right).$$

The main difference of eq. (20) from eq. (3) is due to the terms containing $\cos \left[ \sqrt{K} (\tilde{q}_i - \tilde{q}_j) \tilde{\chi}_N \right]$, that violate the RG invariance. Nevertheless, this invariance approximately holds, since the respective sums
are dominated by the terms with \( i = j \). Working within this approximation and making use of the identity \( \sum_i q_i^\alpha q_i^\beta = \frac{N}{2} \delta^{\alpha\beta} \), we obtain

\[
Z_A \simeq \int_{0 < p < N} \mathcal{D}\vec{\chi}(p)\mathcal{D}\bar{\psi}(p) \exp \left\{ \frac{1}{2} \int d^2 x \psi_N^\prime \left( \partial^2 - m_H^2 \right) \psi_N + \right.
\]

\[
+ a_3 \frac{N(N-1)}{2} (\xi A(0)B(0))^2 \left( 1 + \frac{\Lambda^2}{m_H^2} \right) \frac{N}{2} V + 2\xi A(0)B(0) \int d^2 x \sqrt{K} \psi_N^\prime \sum_i \cos \left( \sqrt{K} \bar{q}_i \bar{\chi}_N \right) - \frac{1}{2} \int d^2 x \left[ 1 + \left( 1 + \frac{\Lambda^2}{m_H^2} \right) \frac{NKa_2}{4} (\xi A(0)B(0))^2 \right] \left( \partial_\mu \bar{\chi}_N^\prime \right)^2 \right\}. \tag{27}
\]

This expression has again been derived in the leading order of the cumulant expansion applied in the course of the average over \( \psi \).

The shift of the free-energy density stemming from eq. (27) [cf. eq. (11)] reads

\[
F^{\text{new}} - F \simeq a_3 \frac{N(N-1)}{2} (\xi A(0)B(0))^2 \left( 1 + \frac{K \Lambda^2}{2\pi m_H^2} \right). \tag{28}
\]

As far as the renormalization of fields and coupling constants is concerned, it is given by eq. (10), where the first equation should be modified as \( \bar{\chi}_N^{\text{new}} = C\bar{\chi}_N \), and the parameter \( C \) from eq. (10) now reads

\[
C = \sqrt{1 + \frac{KNa_2}{4} (\xi A(0)B(0))^2 \left( 1 + \frac{\Lambda^2}{m_H^2} \right)} \simeq \sqrt{1 + \frac{KNa_2}{4} (\xi A(0)B(0))^2 \left( 1 + \frac{\Lambda^2}{m_H^2} \frac{K}{2\pi} \right)}. \tag{29}
\]

From eqs. (28) and (29) we deduce that in the \( SU(N) \)-case the RG flow of couplings and of the free-energy density is identical to that of the \( SU(2) \)-case. Indeed, all the \( N \)-dependence can be absorbed into the constants \( \alpha_{2,3} \) by rescaling them as \( \bar{\alpha}_2 \equiv N\alpha_2/2, \bar{\alpha}_3 = (N-1)\alpha_3/2 \) and further redefining [cf. the notations introduced after eq. (18)] \( \bar{\xi} = (8\pi)^2 \bar{\alpha}_2 y^2 \) and \( \bar{a}^{\text{new}} = a\sqrt{8\pi\bar{\alpha}_2/\bar{\alpha}_3} \). In particular, the critical temperature \( T_c \) remains the same as in the \( SU(2) \)-case. (This follows also from the estimate of the mean squared separation in the monopole-antimonopole molecule, if one takes into account that the square of any root vector is equal to unity.) Thus, the principal difference of the \( SU(N) \)-case, \( N > 2 \), from the \( SU(2) \)-one is that while in the \( SU(2) \)-case the RG invariance is exact (modulo the negligibly small higher-order terms of the cumulant expansion applied to the average over \( \psi \)), in the \( SU(N) \)-case it is only approximate, even in the compact-QED limit of the model.

4 Conclusions.

In the present letter, we have explored the influence of the Higgs field to the RG flow in the finite-temperature 3D Georgi-Glashow model and in its \( SU(N) \)-generalization. In this investigation, the effects of W-bosons have been disregarded, and the analysed RG flow describes the BKT phase transition in the monopole ensemble (rather than the real deconfining phase transition, for whose dynamics W-bosons play the crucial rôle). Further, the Higgs-field mass, \( m_H \), was supposed to be large, namely of the order of the W-boson one, but not infinite, as it takes place in the compact-QED limit of the
model. There have been derived the leading $(\Lambda/m_H)$-corrections (where $\Lambda$ is the momentum scale we are working at) to the standard BKT RG flow in the vicinity of the critical point. In particular, it turned out that the correction to the magnetic coupling constant of the dimensionally-reduced theory is inversely proportional to the second power of the correlation radius and therefore vanishes at the critical point. Besides that, there has been derived the RG equation describing the evolution of $m_H$ itself, which shows that $m_H$ evolves so weakly in the vicinity of the critical point that it can be treated as a constant with a high accuracy. It also turned out that the derived corrections to the RG flow do not affect the position of the critical point. In particular, the value of the BKT critical temperature remains unchanged if one accounts for the finiteness of the Higgs-boson mass. The RG equation describing the evolution of the free-energy density with the account for the Higgs-inspired correction has also been derived. According to this equation, the free-energy density remains continuous in the critical region, and the above-mentioned correction does not violate this property. It has further been demonstrated that contrary to the $SU(2)$-case, in the $SU(N)$-model at $N > 2$, the RG invariance holds only approximately, even in the compact-QED limit. Namely, it holds modulo the approximation $\sum_{ij} f_{ij} \cos [(\vec{q}_i - \vec{q}_j) \cdot \vec{\chi}] \simeq \sum_i f_{ii}$, where $\vec{q}_i$'s are the positive root vectors of the group $SU(N)$. Within this approximation, the RG flow (and consequently, the critical temperature) in the $SU(N)$-model is identical to the one of the $SU(2)$-case, since all the $N$-dependence can then be removed upon the appropriate rescaling.
