Abstract

Within the Standard Model, a review of the current determination of the CKM unitarity triangle parameters is presented, using experimental constraints from the measurements of $|\epsilon_K|, |\frac{V_{cb}}{V_{ub}}|, \Delta m_d$ and from the limit on $\Delta m_s$, available by end 1999.

1 Introduction

This paper contains an update of the determination of the CKM parameters, mainly $\rho$ and $\eta$, of the Wolfenstein parametrization and of the angles of the unitarity triangle, using experimental results and theoretical estimates available at the end of 1999. Previous analyses using the same approach can be found in [1, 2]. Other determinations of these parameters can be found in [3]. As compared to end 1998, new experimental results concern mainly first averages of LEP measurements of $|V_{cb}|$ and $|V_{ub}|$ [4] and an improved limit on $\Delta m_s$ [5].

2 Determination of the $CKM$ unitarity triangle parameters in the Standard Model framework

Results have been obtained using the constraints from the measurements of $|\epsilon_K|, |\frac{V_{cb}}{V_{ub}}|, \Delta m_d$ and $\Delta m_s$. The central values and the uncertainties for the relevant parameters used in this analysis are given in Table 1. As compared with the similar analysis done in [1], the following changes have been made:

i) the uncertainty on $|V_{cb}|$ [4] has been increased from $1.5 \times 10^{-3}$ to $1.9 \times 10^{-3}$. This uncertainty is entirely dominated by theoretical errors and the current belief is that these errors amount to 5% [5]. The quoted central value for $|V_{cb}|$, in Table 1, corresponds to the present LEP
average of $|V_{cb}|$ measurements from inclusive and exclusive B semileptonic decays. Correlations between theoretical errors explain why the quoted uncertainty happens to be slightly below 5%.

ii) the values quoted for the ratio $\frac{|V_{ub}|}{|V_{cb}|}$ have been obtained using the value of $|V_{cb}|$ mentioned before and the values of $|V_{ub}|$ measured at CLEO with exclusive decays and at LEP from inclusive analyses.

iii) The limit on $\Delta m_s$, $\Delta m_s > 14.3$ ps$^{-1}$ at 95% C.L. [3], is higher than the one quoted at the EPS-HP99 Conference after the addition of recent measurements from the SLD Collaboration. The sensitivity [3] of present measurements is equal to 14.5 ps$^{-1}$.

Table 1: Values of the most relevant quantities entering into the expressions of $|\epsilon_K|$, $\frac{|V_{ub}|}{|V_{cb}|}$, $\Delta m_d$ and $\Delta m_s$. In the third column the Gaussian and the flat part of the errors are given explicitly.

2.1 Values of $\vartheta$, $\varpi$ and of the angles of the unitarity triangle

The region in the $(\vartheta, \varpi)$ plane selected by the measurements of $|\epsilon_K|$, $\frac{|V_{ub}|}{|V_{cb}|}$, $\Delta m_d$ and from the limit on $\Delta m_s$, is given in Figure 4. The measured values of the two parameters are:

$$\vartheta = 0.240^{+0.057}_{-0.047}, \quad \varpi = 0.335 \pm 0.042$$

Fitted values for the angles of the unitarity triangle have been also obtained:

$$\sin(2\beta) = 0.750^{+0.058}_{-0.064}, \quad \sin(2\alpha) = -0.38^{+0.24}_{-0.28} \text{ and } \gamma = (55.5^{+6.9}_{-8.5})^\circ.$$ (2)

The accuracy on $\sin 2\beta$ obtained with the present analysis, is better than the one expected from B factories but it is valid only in the Standard Model framework. First measurements of $\sin(2\beta)$ are now available. The world average is: $\sin(2\beta) = 0.91 \pm 0.35$ [3]. The 68% C.L. region is shown in Figure 3 and the constraints on $\vartheta$ and $\varpi$ from this measurement are shown in Figure 3.

The angle $\gamma$ is known with a 15% relative error. Values of $\gamma > 90^\circ$ (or $\vartheta < 0$) are excluded at 99.6% C.L.. The origin of asymmetric errors on $\vartheta$, $\gamma$ and $\sin 2\beta$ is that the information brought by the limit on $\Delta m_s$ is quite efficient in constraining values of $\Delta m_s$ up to 15 ps$^{-1}$ but no information can be obtained for values above 20 ps$^{-1}$.
Figure 1: The allowed region for $\bar{\rho}$ and $\bar{\eta}$ using the parameters listed in Table 1. The contours at 68% and 95% are shown. The full lines correspond to the central values of the constraints given by the measurements of $|V_{ub}|$, $|V_{cb}|$, $|\epsilon_K|$ and $\Delta m_d$. The dotted curve (which is hidden behind the curve of $\Delta m_d$) corresponds to the 95% C.L. upper limit obtained from the experimental limit on $\Delta m_s$.

Figure 2: The $\sin 2\alpha$ and $\sin 2\beta$ distributions have been obtained using the constraints corresponding to the values of the parameters listed in Table 1. The dark-shaded and the clear-shaded intervals correspond, respectively, to 68% and 95% confidence level regions. The lines corresponding to the $\pm 1\sigma$ errors from the measurement of $\sin 2\beta$ using $J/\Psi, K^0_s$ events are also shown. The line obtained for $\gamma = 90^\circ$ is also drawn ($\sin 2\beta = \sin 2\alpha$).
Figure 3: The allowed region for $\bar{\rho}$ and $\bar{\eta}$ using the parameters listed in Table 1. The contours at 68% and 95% are shown. The constraint from $|\epsilon_K|$ has not been used and the dotted lines correspond to 68% C.L. The lines corresponding to the $\pm1\sigma$ errors from the measurement of $\sin2\beta$ using $J/\Psi, K^0_s$ events are also shown ($\sin2\beta=0.91\pm0.35$) [9].

The values of the non-perturbative QCD parameters can be also obtained:

$$f_B\sqrt{B_B} = (232 \pm 13)\text{MeV} \quad ; \quad B_K = 0.80^{+0.15}_{-0.17}$$

after having removed, in turn, these constraints from the analysis. It can be noticed that $f_B\sqrt{B_B}$ is better determined than the present evaluation of this parameter from lattice QCD calculations (Table 1). As a consequence, it is important to observe, contrarily to common belief, that a large uncertainty attached to $f_B\sqrt{B_B}$ has no real impact on the present analysis. Evaluation of this parameter with 5-10% relative error is needed to bring additional information. On the contrary, the parameter $B_K$ is determined with a 20% relative error using the other constraints. The present estimate of this parameter from lattice QCD calculations, given in Table 1, has thus an impact on the present analysis.

A region of the $(\bar{\rho}, \bar{\eta})$ plane can be selected without using the $|\epsilon_K|$ constraint [10]. The result is shown in Figure 3. This test shows that the $(\bar{\rho}, \bar{\eta})$ region selected by the measurements in the B sector (of the two sides of the unitarity triangle) is very well compatible with the region selected from the measurement of CP violation in the kaon sector. Using B decay and oscillations properties only, the values of $\bar{\eta}=0.325\pm 0.054$ and $\sin2\beta=0.747^{+0.067}_{-0.084}$ are determined.

3 Often asked questions

We would like to dedicate this section to two often asked questions.

Question 1: The results from this analysis are precise since, both from the constraints and for the parameters, Gaussian distributions have been taken for the experimental and the theoretical errors.

The answer is that we do not use only Gaussian distributions! Values for the different parameters entering into the equations of constraints are extracted using random generations from Gaussian/non Gaussian distributions depending on the source of the error (Table 1). This has been shown at several seminars and conferences and explained in detail in [1]. For any parameter...
or constraint, entering into the fitting procedure, a detailed study has been done [1, 2].

**Question 2:** How the results are affected if theoretical errors are multiplied by a factor 2?

We believe that the aim of this work is to try to use at best the available measurements and theoretical estimates. Nevertheless it is a simple basic exercise to quantify the dependence of the uncertainties on the final results from the variation of the errors attached to the different quantities used in the analysis. This was already done in [2, 3]. The exercise presented here consists in multiplying by a factor two all the ranges (flat distributions) used for the theoretical estimates given in Table 1 and taking for $V_{cb}$ an error of $\pm 3.0 \times 10^{-3}$. Multiplying theoretical errors by a factor two seems to be rather extreme. In some cases (as for $V_{cb}$ or some lattice QCD parameters) this is equivalent to ignore more than 10 years of theoretical efforts. Just two examples. For the extraction of $V_{cb}$ using exclusive decays $B \rightarrow D^* \ell^{-} \bar{\nu}_{\ell}$, the conservative value of $F_{B^+}(w = 1) = 0.90 \pm 0.05$ has been already taken (in [1] the suggested value is $0.913 \pm 0.042$). In the following exercise the error of $\pm 0.10$ is used! In this exercise the theoretical error on $f_{BV}\sqrt{B_B}$, coming from the evaluation of the quenched approximation, is taken to be $\pm 62$ MeV. This type of errors circulated within the Lattice QCD community in the late ’80. Table 2 summarizes the results of this exercise. As a general conclusion, if theoretical errors on all the parameters given in Table 1 are simultaneously multiplied by a factor 2, the errors on the values of $\overline{\rho}$, $\overline{\eta}$, $\sin2\beta$, $\sin2\alpha$ and $\gamma$ increase by only a factor 1.5.

**Table 2:** Errors on $\overline{\rho}$, $\overline{\eta}$, $\sin2\beta$, $\sin2\alpha$ and $\gamma$ obtained after multiplying by a factor 2 the flat part of theoretical errors given in Table 1 for the parameters mentioned in the first column. Inside brackets, values corresponding to the 95\% C.L. are also given.

4 Conclusions

Impressive improvements have been accomplished during the last ten years in B physics. Figure 4 illustrates the progress on the measurements of the two sides of the Unitarity Triangle. Some conclusions can be drawn. The selected region in the ($\rho$, $\eta$) plane, using B physics only, is very well compatible with the measurement of CP violation in the Kaon system. $\sin^2\beta$ is measured with an accuracy better than 10% within the SM framework. The angle $\gamma$ is smaller than 90° at 99.6% C.L.. This result is very slightly affected by multiplying theoretical errors by a factor two and is essentially due to the impressive improvement on the limit on $\Delta m_s$ obtained during the last 4 years.

The situation will still improve by summer 2000. Thanks to the achieved accuracy, future measurements of CP violation in the B sector would further test the consistency of the Standard Model by determining directly the angles of the Unitarity Triangle.

Figure 4: The allowed region for $\rho$ and $\eta$ from 1988 to the end of 1999

Acknowledgements

Many thanks to the organizers for arranging such a nice Conference in a very stimulating atmosphere. The speaker has benefited from useful discussions with R. Forty, T. Nakada, R. Peccei, S. Willocq and M. Zito; they are warmly thanked.
